

SUPER-LITE INSECT BARRIER

The ability of Super-Lite Insect Barrier to provide an effective barrier to several previously hard to control garden pests is remarkable. This fabric was developed specifically as an insect barrier. With previous row covers, insect control was an unexpected side benefit. Heat build-up was an especially troublesome problem with some crops. Super-Lite Insect Barrier was designed to avoid heat build-up. It is now possible to leave the cover on from seed to harvest. Be sure that plants are not covered during blossoming. Bees must be able to pollinate flowers so that plants will set fruit. (Crops like carrots, broccoli, radishes, etc. which are not grown for their fruit or seed can remain covered up to a week before harvest without concern for pollination during blossoming). It is important to put covers on early, so that small larvae or eggs of pests are not already on plants, row covers can actually make matters worse by providing an environment where pests are protected from their natural enemies.

APPLICATION NOTES: Be sure that there is plenty of slack to allow for plant growth. To apply, simply place cover over row and cover 6 to 10 inches of each edge with soil, or use "U" pins, which make removal and repositioning easier. (By folding over the cover's edge to make a triple thickness, you can reduce fabric tearing).

#2001....8 ft x 20 ft
